# **Machine Learning Engineer Nanodegree**

#### **Model Evaluation & Validation**

### **Project 1: Predicting Boston Housing Prices**

Welcome to the first project of the Machine Learning Engineer Nanodegree! In this notebook, some template code has already been written. You will need to implement additional functionality to successfully answer all of the questions for this project. Unless it is requested, do not modify any of the code that has already been included. In this template code, there are four sections which you must complete to successfully produce a prediction with your model. Each section where you will write code is preceded by a **STEP X** header with comments describing what must be done. Please read the instructions carefully!

In addition to implementing code, there will be questions that you must answer that relate to the project and your implementation. Each section where you will answer a question is preceded by a **QUESTION X** header. Be sure that you have carefully read each question and provide thorough answers in the text boxes that begin with "**Answer:**". Your project submission will be evaluated based on your answers to each of the questions.

A description of the dataset can be found <u>here (https://archive.ics.uci.edu/ml/datasets/Housing)</u>, which is provided by the **UCI Machine Learning Repository**.

# **Getting Started**

To familiarize yourself with an iPython Notebook, **try double clicking on this cell**. You will notice that the text changes so that all the formatting is removed. This allows you to make edits to the block of text you see here. This block of text (and mostly anything that's not code) is written using <u>Markdown (http://daringfireball.net/projects/markdown/syntax)</u>, which is a way to format text using headers, links, italics, and many other options! Whether you're editing a Markdown text block or a code block (like the one below), you can use the keyboard shortcut **Shift + Enter** or **Shift + Return** to execute the code or text block. In this case, it will show the formatted text.

Let's start by setting up some code we will need to get the rest of the project up and running. Use the keyboard shortcut mentioned above on the following code block to execute it. Alternatively, depending on your iPython Notebook program, you can press the **Play** button in the hotbar. You'll know the code block executes successfully if the message "Boston Housing dataset loaded successfully!" is printed.

```
In [1]:
        # Importing a few necessary libraries
        import numpy as np
        import matplotlib.pyplot as plt
        from sklearn import datasets
        from sklearn.tree import DecisionTreeRegressor
        # Make matplotlib show our plots inline (nicely formatted in the noteboo
        k)
        %matplotlib inline
        # Create our client's feature set for which we will be predicting a sell
        ing price
        CLIENT FEATURES = [[11.95, 0.00, 18.100, 0, 0.6590, 5.6090, 90.00, 1.38]
        5, 24, 680.0, 20.20, 332.09, 12.13]]
        # Load the Boston Housing dataset into the city data variable
        city_data = datasets.load_boston()
        # Initialize the housing prices and housing features
        housing prices = city data.target
        housing_features = city_data.data
        print "Boston Housing dataset loaded successfully!"
```

Boston Housing dataset loaded successfully!

# **Statistical Analysis and Data Exploration**

In this first section of the project, you will quickly investigate a few basic statistics about the dataset you are working with. In addition, you'll look at the client's feature set in CLIENT\_FEATURES and see how this particular sample relates to the features of the dataset. Familiarizing yourself with the data through an explorative process is a fundamental practice to help you better understand your results.

### Step 1

In the code block below, use the imported numpy library to calculate the requested statistics. You will need to replace each None you find with the appropriate numpy coding for the proper statistic to be printed. Be sure to execute the code block each time to test if your implementation is working successfully. The print statements will show the statistics you calculate!

```
In [2]: # Number of houses in the dataset
        total houses = housing features.shape[0]
        # Number of features in the dataset
        total_features = housing_features.shape[1]
        # Minimum housing value in the dataset
        minimum price = housing prices.min()
        # Maximum housing value in the dataset
        maximum price = housing_prices.max()
        # Mean house value of the dataset
        mean price = np.mean(housing prices)
        # Median house value of the dataset
        median price = np.median(housing prices)
        # Standard deviation of housing values of the dataset
        std dev = housing_prices.std()
        # Show the calculated statistics
        print "Boston Housing dataset statistics (in $1000's):\n"
        print "Total number of houses:", total_houses
        print "Total number of features:", total_features
        print "Minimum house price:", minimum_price
        print "Maximum house price:", maximum_price
        print "Mean house price: {0:.3f}".format(mean price)
        print "Median house price:", median_price
        print "Standard deviation of house price: {0:.3f}".format(std dev)
```

Boston Housing dataset statistics (in \$1000's):

Total number of houses: 506
Total number of features: 13
Minimum house price: 5.0
Maximum house price: 50.0
Mean house price: 22.533
Median house price: 21.2

Standard deviation of house price: 9.188

#### **Question 1**

As a reminder, you can view a description of the Boston Housing dataset <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), where you can find the different features under <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), where you can find the different features under <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), where you can find the different features under <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), where you can find the different features under <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), where you can find the different features under <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), where you can find the different features under <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), where you can find the different features under <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), where you can find the different features of the values stored in our housing\_prices variable, so we do not consider that a feature of the data.

Of the features available for each data point, choose three that you feel are significant and give a brief description for each of what they measure.

Remember, you can double click the text box below to add your answer!

Answer: Form correlation coefficient and pairs plot, we identified the following three are the significant variables: RM, LSTAT, PTRATIO. RM: Average number of rooms per dwellings (size of the house) LSTAT: % of Lower status of the population PTRATION: pupil teacher ratio (indicators of good school district)

#### **Question 2**

Using your client's feature set CLIENT\_FEATURES, which values correspond with the features you've chosen above?

Hint: Run the code block below to see the client's data.

```
In [3]: print CLIENT_FEATURES

[[11.95, 0.0, 18.1, 0, 0.659, 5.609, 90.0, 1.385, 24, 680.0, 20.2, 332.0
9, 12.13]]
```

**Answer:** 5.609, 20.2,12.13

# **Evaluating Model Performance**

In this second section of the project, you will begin to develop the tools necessary for a model to make a prediction. Being able to accurately evaluate each model's performance through the use of these tools helps to greatly reinforce the confidence in your predictions.

### Step 2

In the code block below, you will need to implement code so that the shuffle\_split\_data function does the following:

- Randomly shuffle the input data X and target labels (housing values) y.
- Split the data into training and testing subsets, holding 30% of the data for testing.

If you use any functions not already acessible from the imported libraries above, remember to include your import statement below as well!

Ensure that you have executed the code block once you are done. You'll know if the shuffle\_split\_data function is working if the statement "Successfully shuffled and split the data!" is printed.

```
In [4]: # Put any import statements you need for this code block here
        def shuffle split data(X, y):
            """ Shuffles and splits data into 70% training and 30% testing subse
        ts,
                then returns the training and testing subsets. """
            np.random.seed(1234)
            np.random.shuffle(X)
            np.random.shuffle(v)
            size=X.shape[0]*.7
            # Shuffle and split the data
            X train = X[:size,]
            y train = y[:size,]
            X test = X[size:,]
            y test = y[size:,]
            # Return the training and testing data subsets
            return X train, y train, X test, y test
        # Test shuffle split data
        try:
            X_train, y_train, X_test, y_test = shuffle_split_data(housing_featur
        es, housing prices)
            print "Successfully shuffled and split the data!"
        except:
            print "Something went wrong with shuffling and splitting the data."
```

Successfully shuffled and split the data!

### **Question 4**

Why do we split the data into training and testing subsets for our model?

**Answer:** To avoid overfitting, the data is splitted into training and testing subsets.

## Step 3

In the code block below, you will need to implement code so that the performance\_metric function does the following:

Perform a total error calculation between the true values of the y labels y\_true and the
predicted values of the y labels y\_predict.

You will need to first choose an appropriate performance metric for this problem. See <u>the sklearn</u> <u>metrics documentation (http://scikit-learn.org/stable/modules/classes.html#sklearn-metrics-metrics)</u> to view a list of available metric functions. **Hint:** Look at the question below to see a list of the metrics that were covered in the supporting course for this project.

Once you have determined which metric you will use, remember to include the necessary import statement as well!

Ensure that you have executed the code block once you are done. You'll know if the performance\_metric function is working if the statement "Successfully performed a metric calculation!" is printed.

```
In [5]: # Put any import statements you need for this code block here
    from sklearn.metrics import mean_squared_error

def performance_metric(y_true, y_predict):
        """ Calculates and returns the total error between true and predicte
        d values
            based on a performance metric chosen by the student. """

        error = mean_squared_error(y_true,y_predict)
        return error

# Test performance_metric
try:
        total_error = performance_metric(y_train, y_train)
        print "Successfully performed a metric calculation!"
    except:
        print "Something went wrong with performing a metric calculation."
```

Successfully performed a metric calculation!

#### **Question 4**

Which performance metric below did you find was most appropriate for predicting housing prices and analyzing the total error. Why?

- Accuracy
- Precision
- Recall
- F1 Score
- Mean Squared Error (MSE)
- Mean Absolute Error (MAE)

**Answer:** In this analysis, we used MSE. Accuracy, Precision, Recall and F1 score are perfomance metrices for classification problems. Since, predicting housing prices is a regression problem, either MSE or MAE can be used as performance metric. MAE is a linear score where all the errors are weighted equally in the average. In MSE, erros are squared before average, therefore, it gives relatively greater weights on the large errors. In this analysis, MSE is used to make the prediction robust against extreme values.

## Step 4 (Final Step)

In the code block below, you will need to implement code so that the fit\_model function does the following:

- Create a scoring function using the same performance metric as in **Step 2**. See the <u>sklearn</u> <u>make\_scorer documentation (http://scikit-</u>
  - <u>learn.org/stable/modules/generated/sklearn.metrics.make\_scorer.html</u>).
- Build a GridSearchCV object using regressor, parameters, and scoring\_function. See the <u>sklearn documentation on GridSearchCV (http://scikit-learn.org/stable/modules/generated/sklearn.grid\_search.GridSearchCV.html)</u>.

When building the scoring function and GridSearchCV object, *be sure that you read the parameters documentation thoroughly.* It is not always the case that a default parameter for a function is the appropriate setting for the problem you are working on.

Since you are using sklearn functions, remember to include the necessary import statements below as well!

Ensure that you have executed the code block once you are done. You'll know if the fit\_model function is working if the statement "Successfully fit a model to the data!" is printed.

```
In [6]: # Put any import statements you need for this code block
        from sklearn.grid_search import GridSearchCV
        from sklearn.metrics import make scorer
        from sklearn.tree import DecisionTreeRegressor
        from sklearn.metrics import mean squared error
        from sklearn import cross_validation
        def fit_model(X, y):
            """ Tunes a decision tree regressor model using GridSearchCV on the
        input data X
                and target labels y and returns this optimal model. """
            # Create a decision tree regressor object
            regressor = DecisionTreeRegressor()
            # Set up the parameters we wish to tune
            parameters = {'max_depth':(1,2,3,4,5,6,7,8,9,10)}
            # Make an appropriate scoring function
            scoring function = make scorer(mean squared error)
            # Make the GridSearchCV object
            reg = GridSearchCV(regressor,parameters,cv = 5, scoring=scoring func
        tion)
            # Fit the learner to the data to obtain the optimal model with tuned
        parameters
            reg.fit(X, y)
            # Return the optimal model
            return reg
        # Test fit model on entire dataset
        try:
            reg = fit model(housing features, housing prices)
            print "Successfully fit a model!"
            print "Something went wrong with fitting a model."
```

Successfully fit a model!

#### **Question 5**

What is the grid search algorithm and when is it applicable?

**Answer:** Grid search is the parameters optimization/tuning algorithm. It is used to find best/optimized parameters for a predictive model

#### **Question 6**

What is cross-validation, and how is it performed on a model? Why would cross-validation be helpful when using grid search?

**Answer:** cross-validation is a model evalution technique. K-Fold cross-validation is one of the widely used cross-validation methods. In k-Fold cross-validation, the data set is divided into k subsets. Then, one of the k subsets is used as the test set and the other k-1 subsets are put together to form a training set. The process continues for k times. Then the average error across all k trials is computed.

Cross-validation will help to avoid overrfitting of the models during grid search.

# **Checkpoint!**

You have now successfully completed your last code implementation section. Pat yourself on the back! All of your functions written above will be executed in the remaining sections below, and questions will be asked about various results for you to analyze. To prepare the **Analysis** and **Prediction** sections, you will need to intialize the two functions below. Remember, there's no need to implement any more code, so sit back and execute the code blocks! Some code comments are provided if you find yourself interested in the functionality.

```
In [7]: def learning curves(X train, y train, X test, y test):
             """ Calculates the performance of several models with varying sizes
        of training data.
                The learning and testing error rates for each model are then plo
        tted.
            print "Creating learning curve graphs for max depths of 1, 3, 6, and
        10. . ."
            # Create the figure window
            fig = plt.figure(figsize=(10,8))
            # We will vary the training set size so that we have 50 different si
        zes
            sizes = np.round(np.linspace(1, len(X train), 50))
            train err = np.zeros(len(sizes))
            test err = np.zeros(len(sizes))
            # Create four different models based on max_depth
            for k, depth in enumerate([1,3,6,10]):
                for i, s in enumerate(sizes):
                    # Setup a decision tree regressor so that it learns a tree w
        ith max depth = depth
                    regressor = DecisionTreeRegressor(max depth = depth)
                    # Fit the Learner to the training data
                    regressor.fit(X_train[:s], y_train[:s])
                    # Find the performance on the training set
                    train err[i] = performance metric(y train[:s], regressor.pre
        dict(X train[:s]))
                    # Find the performance on the testing set
                    test err[i] = performance metric(y test, regressor.predict(X
        _test))
                # Subplot the learning curve graph
                ax = fig.add subplot(2, 2, k+1)
                ax.plot(sizes, test_err, lw = 2, label = 'Testing Error')
                ax.plot(sizes, train_err, lw = 2, label = 'Training Error')
                ax.legend()
                ax.set title('max depth = %s'%(depth))
                ax.set xlabel('Number of Data Points in Training Set')
                ax.set_ylabel('Total Error')
                ax.set xlim([0, len(X train)])
            # Visual aesthetics
            fig.suptitle('Decision Tree Regressor Learning Performances', fontsi
        ze=18, y=1.03)
            fig.tight_layout()
            fig.show()
```

3/10/2016

```
In [8]:
        def model complexity(X train, y train, X test, y test):
             """ Calculates the performance of the model as model complexity incr
        eases.
                The learning and testing errors rates are then plotted. """
            print "Creating a model complexity graph. . . "
            # We will vary the max depth of a decision tree model from 1 to 14
            max depth = np.arange(1, 14)
            train_err = np.zeros(len(max_depth))
            test err = np.zeros(len(max depth))
            for i, d in enumerate(max depth):
                # Setup a Decision Tree Regressor so that it learns a tree with
        depth d
                regressor = DecisionTreeRegressor(max depth = d)
                # Fit the learner to the training data
                regressor.fit(X train, y train)
                # Find the performance on the training set
                train_err[i] = performance_metric(y_train, regressor.predict(X_t
        rain))
                # Find the performance on the testing set
                test err[i] = performance metric(y test, regressor.predict(X tes
        t))
            #total err = train err+test err
            #print total err
            # Plot the model complexity graph
            plt.figure(figsize=(7, 5))
            plt.title('Decision Tree Regressor Complexity Performance')
            plt.plot(max_depth, test_err, lw=2, label = 'Testing Error')
            plt.plot(max depth, train err, lw=2, label = 'Training Error')
            plt.legend()
            plt.xlabel('Maximum Depth')
            plt.ylabel('Total Error')
            plt.show()
```

# **Analyzing Model Performance**

In this third section of the project, you'll take a look at several models' learning and testing error rates on various subsets of training data. Additionally, you'll investigate one particular algorithm with an increasing max\_depth parameter on the full training set to observe how model complexity affects learning and testing errors. Graphing your model's performance based on varying criteria can be beneficial in the analysis process, such as visualizing behavior that may not have been apparent from the results alone.

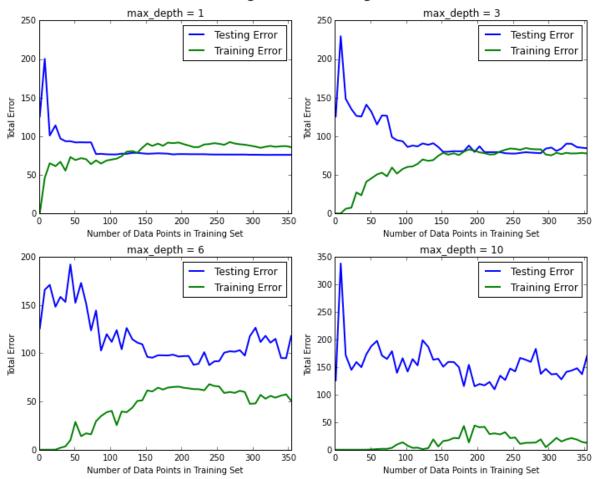

In [10]: learning\_curves(X\_train, y\_train, X\_test, y\_test)

Creating learning curve graphs for max\_depths of 1, 3, 6, and 10. . .

#### Decision Tree Regressor Learning Performances

### **Question 7**

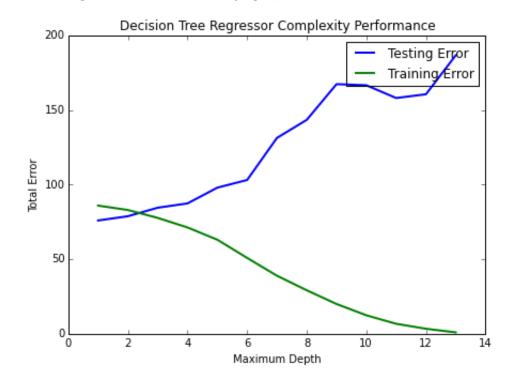

Choose one of the learning curve graphs that are created above. What is the max depth for the chosen model? As the size of the training set increases, what happens to the training error? What happens to the testing error?

**Answer:** The max depth for chosen model is 6. As the training set increases from 150 to 250, both training and testing errors remain steady. As the training set goes above 250, training error reduces slightly but testing error increases.

#### **Question 8**

Look at the learning curve graphs for the model with a max depth of 1 and a max depth of 10. When the model is using the full training set, does it suffer from high bias or high variance when the max depth is 1? What about when the max depth is 10?

**Answer:** For max depth =1, the model suffers from high bias and for max depth = 10, model suffers from high variance.

#### **Question 9**

From the model complexity graph above, describe the training and testing errors as the max depth increases. Based on your interpretation of the graph, which max depth results in a model that best generalizes the dataset? Why?

**Answer:** The training error is maximum for max depth =1 and it decreases as the max depth increases. The training error is minimum for max depth =1 and it increases as the max depth increases. Based on model complexity graph, total error is minimum for max depth = 4, therefore max depth=4 generalizes the dataset best.

### **Model Prediction**

In this final section of the project, you will make a prediction on the client's feature set using an optimized model from fit\_model. To answer the following questions, it is recommended that you run the code blocks several times and use the median or mean value of the results.

#### **Question 10**

Using grid search on the entire dataset, what is the optimal max\_depth parameter for your model? How does this result compare to your intial intuition?

**Hint:** Run the code block below to see the max depth produced by your optimized model.

```
In [21]: print "Final model optimal parameters:", reg.best_params_
Final model optimal parameters: {'max_depth': 10}
```

**Answer:** Final optimal parameter is max\_depth =10. However, from model complexity curve, max\_depth =4 looks optimized. Furthermore, max\_depth=10 model suffers from high variance issue.

#### **Question 11**

With your parameter-tuned model, what is the best selling price for your client's home? How does this selling price compare to the basic statistics you calculated on the dataset?

**Hint:** Run the code block below to have your parameter-tuned model make a prediction on the client's home.

```
In [22]: sale_price = reg.predict(CLIENT_FEATURES)
    print "Predicted value of client's home: {0:.3f}".format(sale_price[0])
```

Predicted value of client's home: 21.613

Answer: The predicted value for client's home is 21.613, which is very close to median selling price.

# **Question 12 (Final Question):**

In a few sentences, discuss whether you would use this model or not to predict the selling price of future clients' homes in the Greater Boston area.

**Answer:** I would not use the parameter-tuned model for predicting the selling price of future clients' homes in the Greater Boston Area because the model is overfit and shows very high variance. In order to make it useful, we need to introduce more training example and use smaller meaningful features.
